

October 2016 through October 2017 NeuLife Programs and Outcomes

It is the mission of NeuLife as an organization to provide a comprehensive program of specialized rehabilitation to support and promote functional improvement and the quality of life for our patients. At NeuLife, our innovative techniques to restoring function and increasing independence can help individuals in multiple areas of daily and community living so the transition home is as successful as possible.

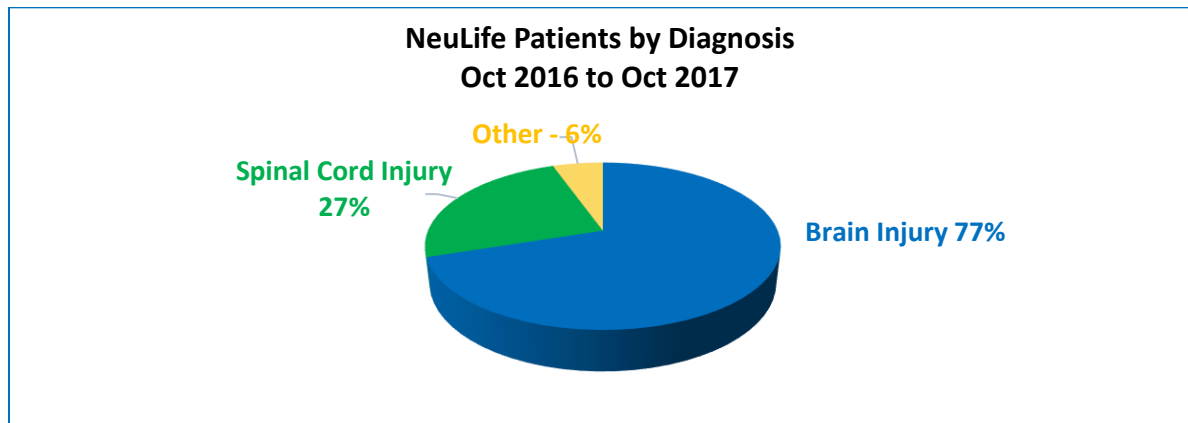

Demographic Facts

Out of 110 patients treated at NeuLife from October 2016 through October 2017, 86 were men and 24 were women. The average age is 47 for men and 39 for women.

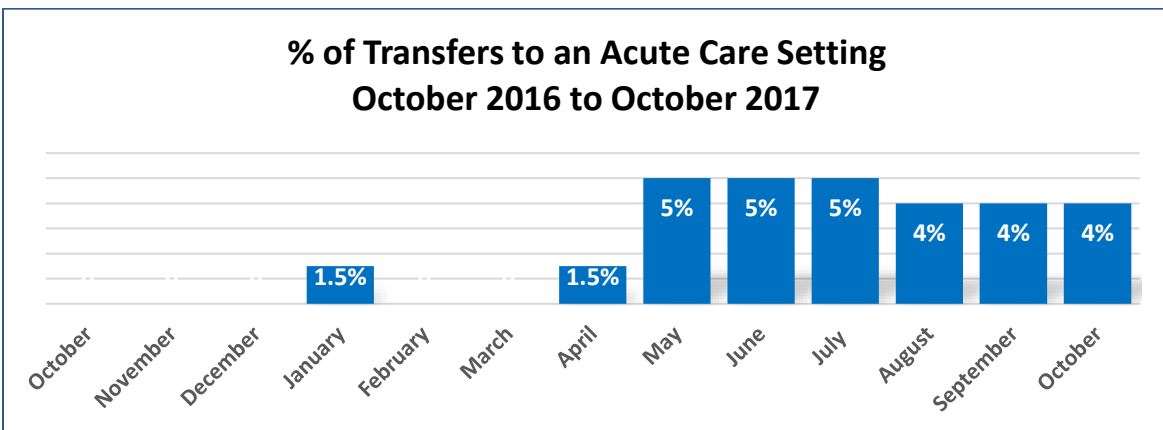

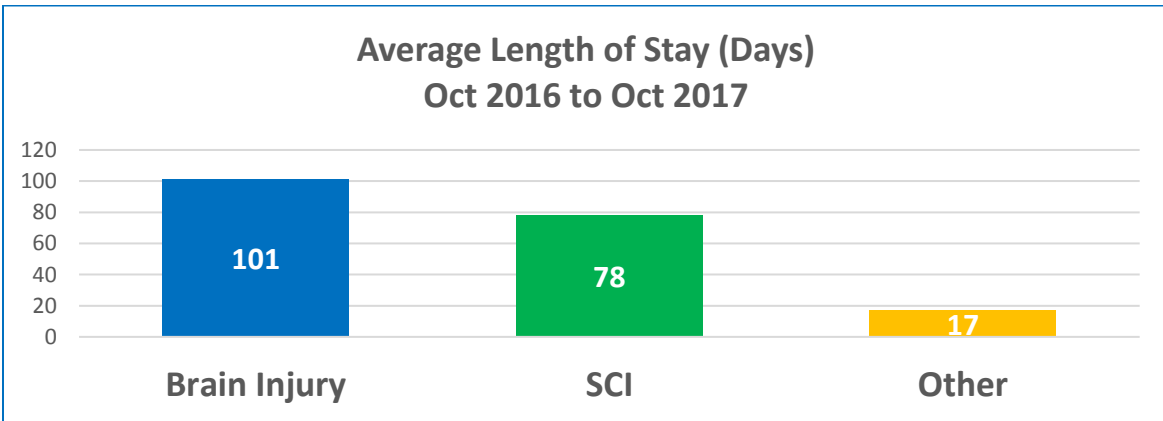

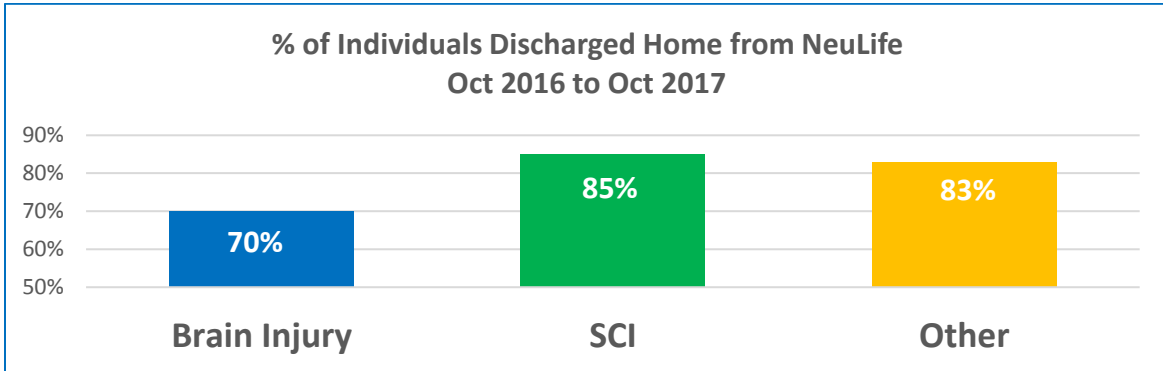

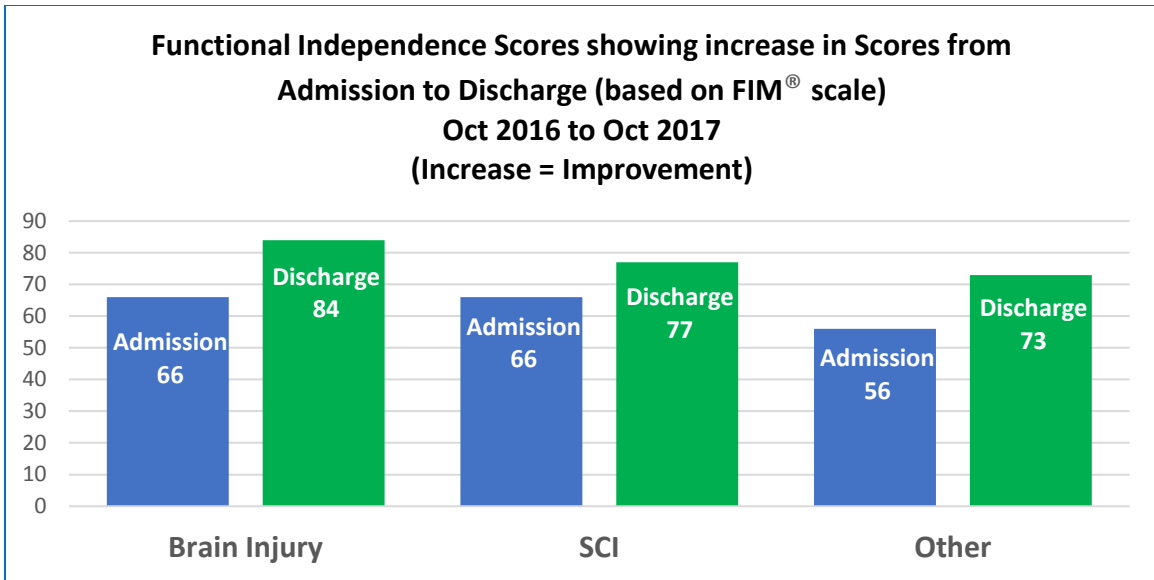

Types of Conditions Treated at NeuLife

77% of the patients treated at NeuLife had brain injuries, while 27% of the patients had spinal cord injuries. Many of these patients have been through catastrophic accidents and suffered multiple injuries causing them to have a dual diagnosis of TBI and SCI, orthopedic injuries or other catastrophic injuries.

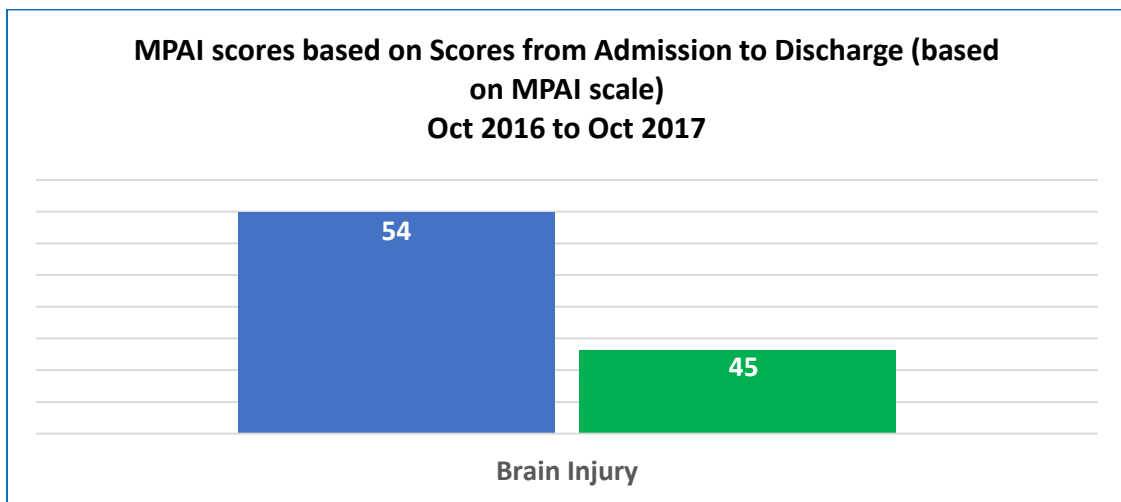

NeuLife provides specialized post-acute rehabilitation to individuals with traumatic brain injury, spinal cord injury and other challenging catastrophic injuries and diagnoses. Our rehabilitation program includes clinical evaluations, medical care and therapeutic activities that are customized to meet the goals, needs and abilities of each patient. These services may include nursing, therapies, neuropsychology, physical medicine and rehabilitation medical management, psychiatry, counseling, vocational/volunteer, wellness/exercise/health, recreation, therapeutic groups and community integration, at an average of 8 hours per day.

The **Functional Independence Measure FIM®** is an assessment tool that evaluates the functional status of patients throughout the rehabilitation process. It allows clinicians to track changes in the functional status of patients from admission to discharge.

The Mayo-Portland Adaptability Inventory (MPAI) is designed to assist in the clinical evaluation of patients during the post-acute period following acquired brain injury (ABI). MPAI items represent the range of physical, cognitive, emotional, behavioral and social problems that patients may encounter after ABI. It also provides an assessment of major obstacles to community integration which may result directly from ABI as well as features of the social and physical environment.
